# Review

---

- What happens when we create a Scanner?
  - `Scanner input = new Scanner(System.in);`
  - `int value = input.nextInt();`
  - `// close the Scanner`

# Overview

---

- Boolean data type
- If statement
- Switch statement

# The boolean Type and Operators

---

Often a program needs to compare two values, such as whether *i* is greater than *j*.

Java provides six comparison operators (aka relational operators) to compare two values. See next slide.

Result of the comparison is a boolean value: true or false.

```
boolean b = (1 > 2) ;
```

Similar to int, float, double, etc., boolean is just another data type.

# Relational Operators

| Java Operator | Mathematics Symbol | Name                     | Example (radius is 5)       | Result             |
|---------------|--------------------|--------------------------|-----------------------------|--------------------|
| <             | <                  | less than                | <code>radius &lt; 0</code>  | <code>false</code> |
| <=            | ≤                  | less than or equal to    | <code>radius &lt;= 0</code> | <code>false</code> |
| >             | >                  | greater than             | <code>radius &gt; 0</code>  | <code>true</code>  |
| >=            | ≥                  | greater than or equal to | <code>radius &gt;= 0</code> | <code>true</code>  |
| ==            | =                  | equal to                 | <code>radius == 0</code>    | <code>false</code> |
| !=            | ≠                  | not equal to             | <code>radius != 0</code>    | <code>true</code>  |

```
boolean b = (1 > 2);
```

true and false are boolean literals

# Logical Operators

---

| Operator | Name         | Description         |
|----------|--------------|---------------------|
| !        | not          | logical negation    |
| &&       | and          | logical conjunction |
|          | or           | logical disjunction |
| ^        | exclusive or | logical exclusion   |

# Truth Table for Operator ! (not)

---

| p     | !p    | Example (assume age = 24, weight = 140)                     |
|-------|-------|---|
| true  | false | !(age > 18) is false, because (age > 18) is true.           |
| false | true  | !(weight == 150) is true, because (weight == 150) is false. |

# Truth Table for Operator && (and)

| $p_1$ | $p_2$ | $p_1 \ \&\& \ p_2$ | Example (assume age = 24, weight = 140)  |
|-------|-------|--------------------|--|
| false | false | false              | $(\text{age} \leq 18) \ \&\& \ (\text{weight} < 140)$ is false, because both conditions are false.                                       |
| false | true  | false              |  |
| true  | false | false              | $(\text{age} > 18) \ \&\& \ (\text{weight} > 140)$ is false, because $(\text{weight} > 140)$ is false.                                   |
| true  | true  | true               | $(\text{age} > 18) \ \&\& \ (\text{weight} \geq 140)$ is true, because both $(\text{age} > 18)$ and $(\text{weight} \geq 140)$ are true. |

# Truth Table for Operator `||` (or)

---

| $p_1$ | $p_2$ | $p_1 \parallel p_2$ | Example (assume age = 24, weihgt = 140)   |
|-------|-------|---------------------|---|
| false | false | false               |   |
| false | true  | true                | $(\text{age} > 34) \parallel (\text{weight} \leq 140)$ is true, because $(\text{age} > 34)$ is false, but $(\text{weight} \leq 140)$ is true. |
| true  | false | true                | $(\text{age} > 14) \parallel (\text{weight} \geq 150)$ is true, because $(\text{age} > 14)$ is true.  |
| true  | true  | true                |   |

# Truth Table for Operator $\wedge$ (exclusive or)

| $p_1$ | $p_2$ | $p_1 \wedge p_2$ | Example (assume age = 24, weight = 140)   |
|-------|-------|------------------|---|
| false | false | false            | $(\text{age} > 34) \wedge (\text{weight} > 140)$ is false, because $(\text{age} > 34)$ is false and $(\text{weight} > 140)$ is false.     |
| false | true  | true             | $(\text{age} > 34) \wedge (\text{weight} \geq 140)$ is true, because $(\text{age} > 34)$ is false but $(\text{weight} \geq 140)$ is true. |
| true  | false | true             | $(\text{age} > 14) \wedge (\text{weight} > 140)$ is true, because $(\text{age} > 14)$ is true and $(\text{weight} > 140)$ is false.       |
| true  | true  | false            |   |

# Short Circuit Evaluation

---

- We stop evaluating a **boolean expression** as soon as its value can be determined
- This happens when have a compound expressions involving **&&** and **||**
  - **&&** - stop once an expression that evaluated to false is found
  - **||** - stops once an expression that evaluates to true is found
  - Example: Boolean1.java

# Order of Operators (Section 3.15)

---

- Anything in parentheses
- `expr++ expr--` (postfix)
- `+ - ++expr --expr` (unary plus/minus, prefix)
- (type) (Casting)
- **!** (**not**)
- `* / %` (multiplication, division, remainder)
- `+ -` (binary addition, subtraction)
- `< <= > >=` (relational operators)
- `== !=` (equality)
- `^` (**exclusive or**)
- `&&` (**and**)
- `||` (**or**)
- `= += -= *= /= %=` (assignment, augmented assignment)

Let's see `Boolean1.java` as an example

# Selection Statements

---

- Homework 1, Question 4 we assumed  $r > 0$ 
  - Calculate surface area of a sphere with radius  $r$  (user input)
  - Everything is fine as long as  $r$  is a positive number
- What if the user input is a negative number?
  - Write code that can handle user input that is not correct
- Types of selection statements
  - if statement
  - switch statement

# If Statement

---

- Select a path of execution based on a condition
  - A condition is evaluated (i.e. boolean expression)
  - If the condition is true
    - ▶ The statements in the true branch are executed
  - If the condition is false
    - ▶ The statements in false branch are executed (if there is an "else")

# One-way if Statements

---

```
if (boolean-expression) {  
    statement(s);  
}
```

# One-way if Statements

---

```
if i > 0 {  
    System.out.println("i is positive");  
}
```

(a) Wrong

```
if (i > 0) {  
    System.out.println("i is positive");  
}
```

(b) Correct

```
if (i > 0) {  
    System.out.println("i is positive");  
}
```

(a)

Equivalent

```
if (i > 0)  
    System.out.println("i is positive");
```

(b)

- But only one statement can omit {}
- Let's see code Boolean2.java, Even1.java

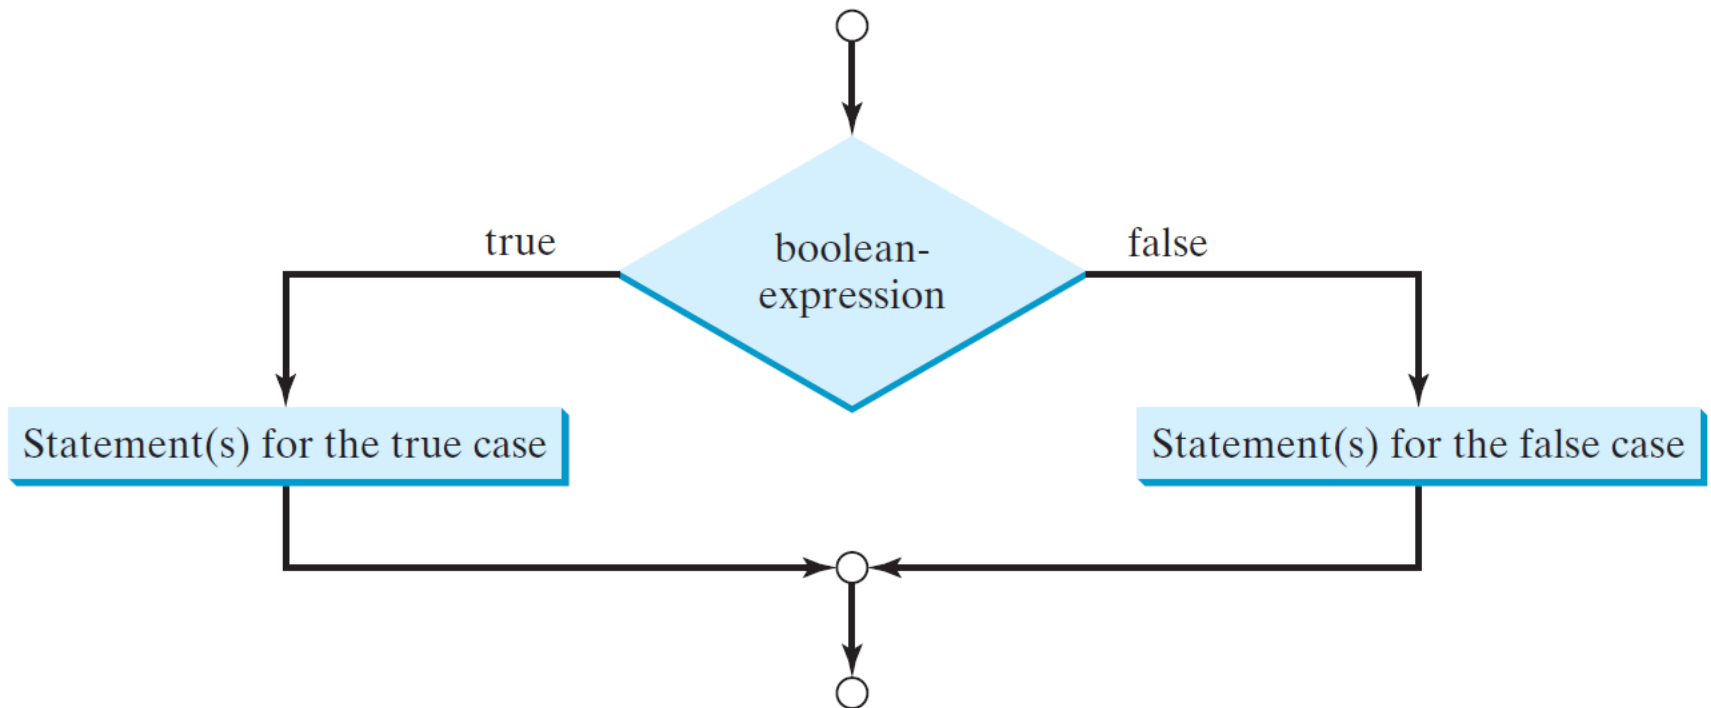

# Two-way if Statement

```
if (boolean-expression) {  
    statement(s)-for-the-true-case;  
}  
else {  
    statement(s)-for-the-false-case;  
}
```

Example: Even2.java

# Multiple Alternative if Statements

```
if (score >= 90.0)
    System.out.print("A");
else
    if (score >= 80.0)
        System.out.print("B");
    else
        if (score >= 70.0)
            System.out.print("C");
        else
            if (score >= 60.0)
                System.out.print("D");
            else
                System.out.print("F");
```

(a)

Equivalent

```
if (score >= 90.0)
    System.out.print("A");
else if (score >= 80.0)
    System.out.print("B");
else if (score >= 70.0)
    System.out.print("C");
else if (score >= 60.0)
    System.out.print("D");
else
    System.out.print("F");
```

This is better

(b)

The else clause matches the **most recent** if clause  
Example: ComputeAndInterpretBMI.java

# Problem: Body Mass Index

---

Body Mass Index (BMI) is a measure of health on weight. It can be calculated by taking your weight in kilograms and dividing by the square of your height in meters. The interpretation of BMI for people 16 years or older is as follows:

| BMI                           | Interpretation |
|-------------------------------|----------------|
| $\text{BMI} < 18.5$           | Underweight    |
| $18.5 \leq \text{BMI} < 25.0$ | Normal         |
| $25.0 \leq \text{BMI} < 30.0$ | Overweight     |
| $30.0 \leq \text{BMI}$        | Obese          |

# If statement notes

---

- The else clause matches the most recent if clause

```
int i = 1, j = 2, k = 3;

if (i > j)
  if (i > k)
    System.out.println("A");
  else
    System.out.println("B");
```

(a)

Equivalent

---

---

This is better  
with correct  
indentation

```
int i = 1, j = 2, k = 3;

if (i > j)
  if (i > k)
    System.out.println("A");
  else
    System.out.println("B");
```

(b)

- What's the output?

# If statement notes

---

To force the else clause to match the first if clause, must add a pair of braces:

```
int i = 1, j = 2, k = 3;
if (i > j) {
    if (i > k)
        System.out.println("A");
}
else
    System.out.println("B");
```

# If statement summary

---

- Block statements `{}` can be omitted if there is only one statement
- Recommendation
  - **Use curly braces: it helps make the code easier to modify and less error prone**
- Avoid deeply nested if statements
- An "else" clause always belongs with the most recent if clause

# Summary

---

- Numeric literals
- Data casting
- Boolean data type
- If statement
